Any one of these curves can be drawn to have four-pointic contact with a given curve at any point, and, if the curve be such that the pole of the osculating spiral (S) lie always on the radius vector, the locus of S will be the inverse of the given curve with respect to the origin. If the chord of curvature through the pole be  $kr$ , it will be found that  $dp/ds = (k-1)\cot \angle OPY$  (when S lies on OP), whence  $r^2 - 3r = a^2 - oA - dp$  will be the equation for a curve such that the locus of the pole of the osculating spiral is the inverse, with respect to the circle  $r = A^2$ , of the curve. If the constant term in this equation be omitted, it is the equation between  $r$  and  $p$  for the spiral. Perhaps the equation would be better, written in the form  $r^2 - 2r = a^2 + (p/c) + V$ , since  $k = 2$  (the equiangular spiral) would give  $r^2 = p + A^2$ , or the involute of a circle which is only a particular case. If we put  $k = -2$ , the osculating curve is the rectangular hyperbola, and the curve is a central conic. That is, if the rectangular hyperbola of four-point contact be drawn at each point of a central conic, the locus of its centre (the pole in this case) is the inverse of the conic with respect to the director circle. No doubt, other particular cases may be readily investigated, such as...
